An introduction to Generalized Linear Models (GLMs)

FW 891

Christopher Cahill 11 September 2023

Purpose

- Introduce design matrices for linear models
- Introduce Generalized Linear Models
 - In particular, the Poisson and binomial GLMs
- Simulate fake data from these models
- Write Stan code to estimate the parameters of these models
- A fun question

Breaking statistical models down

response = deterministic component + random component

 This section / lecture is based heavily on Kery and Schaub 2012; Kery and Royle 2016

The random (noise) component

- Hallmark of statistical models: they must account for randomness
- Check out ?ddist in R, and replace dist by any of the following: pois, binom, norm, multinom, exp, and unif
- Changing first letter d to p, q, or r allows one to get the density, the distribution function, the percentiles, and random numbers from these distributions, respectively.
 - Note R calls mass functions density functions (e.g., dbinom())

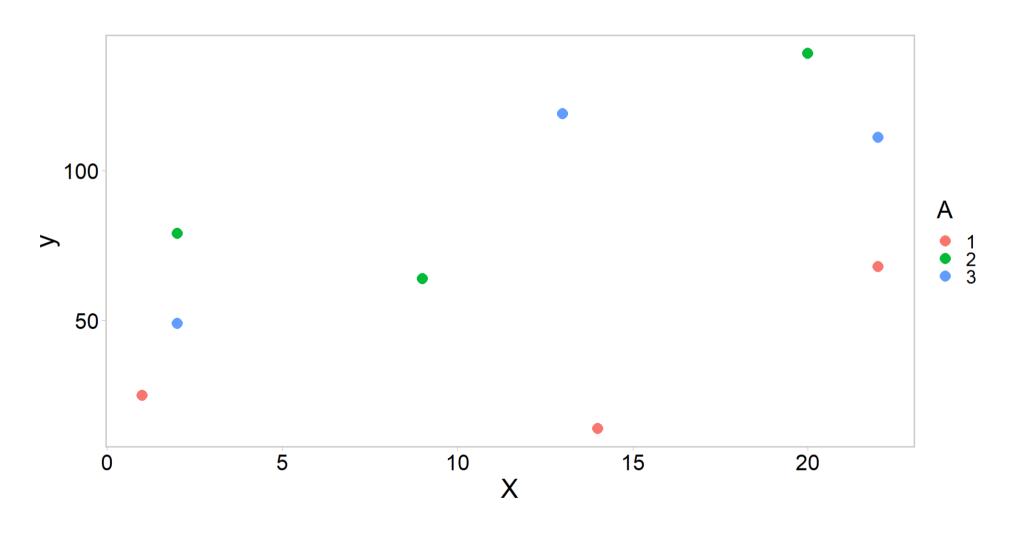

The deterministic (signal) component

- The signal component of the model contains the predictable parts of a response or the mean structure of a model
- Often the mean structure is described by a linear model, although nonlinear models can also be used (Seber and Wild 2003)
- Linear model is just one specific way to describe how we imagine our explantory variables influencing our repsonse
- This model is linear in the parameters and does not need to represent a straight line when plotted
- t-test, simple and multiple linear regressions, ANOVA, ANCOVA, and many mixed models are all linear models

A brief illustration of an analysis of covariance ANCOVA

```
1 library(tidyverse)
2 library(ggqfc)
3 y <- c(25, 14, 68, 79, 64, 139, 49, 119, 111) # obs
4 A <- factor(c(1, 1, 1, 2, 2, 2, 3, 3, 3)) # group
5 X <- c(1, 14, 22, 2, 9, 20, 2, 13, 22) # covariate
6 my_df <- data.frame(y, A, X)
7
8 my_df %>%
9 ggplot(aes(X, y, color = A)) +
10 geom_point(pch = 16, size = 3.5) + theme_qfc()
```

A brief illustration of an analysis of covariance ANCOVA

Running the (Frequentist) ANCOVA in R

```
1 lm(y ~ A - 1 + X)

Call:
lm(formula = y ~ A - 1 + X)

Coefficients:
    A1     A2     A3     X
1.315    65.218    58.648    2.785
```

- This so-called "formula language" is clever because it is quick and error-free if you know how to specify your model
- What does y ~ A-1 + X actually mean?

ANCOVA maths

When we fitted that model, we were doing the following:

$$y_i = eta_{g(i)} + eta_1 \cdot X_i + arepsilon_i \quad ext{where} \quad arepsilon_i \sim \mathrm{N}ig(0, \sigma^2ig)$$

- y_i is a response of unit (data point, individual, row) i, X_i is the value of the continuous explanatory variable x for unit i
- Factor A codes for the group membership of each unit with indeces g for groups 1,2, or 3
- ullet Two parameters in the mean relationship, $eta_{g(i)}$ and eta_1
 - First of these is a vector, second a scalar
 - Index g indicates group 1, 2, or 3

ANCOVA maths: one way

$$y_i = eta_{g(i)} + eta_1 \cdot X_i + arepsilon_i \quad ext{where} \quad arepsilon_i \sim ext{N}ig(0, \sigma^2ig)$$

- The random (noise) part of the model consists of the part of the response which we cannot explain using our linear combination of explanatory variables
 - Represented by residuals $arepsilon_i$
 - Assume they come from a normal distribution with common variance σ^2
- How many parameters in total does this model have?

ANCOVA maths another way

Old way:

$$y_i = eta_{g(i)} + eta_1 \cdot X_i + arepsilon_i \quad ext{where} \quad arepsilon_i \sim \mathrm{N}ig(0, \sigma^2ig)$$

Shifting the structure of the model via algebra:

$$y_i \sim \mathrm{N}ig(eta_{g(i)} + eta_1 \cdot X_i, \sigma^2ig).$$

ANCOVA maths even more ways

A further possibility:

$$y_i \sim ext{N}ig(\mu_i, \sigma^2ig), \quad where \quad \mu_i = eta_{g(i)} + eta_1 \cdot X_i$$

- Being able to write a linear model in algebra helps code the model in Stan (or any other modeling platform)
- Also helps you understand commonalities between many common statistical tests and what lm() in R is doing

ANCOVA: but wait, there's more 😂

The same model via matrix and vector notation:

$$\begin{pmatrix} 25 \\ 14 \\ 68 \\ 79 \\ 64 \\ 139 \\ 49 \\ 119 \\ 111 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 14 \\ 1 & 0 & 0 & 22 \\ 0 & 1 & 0 & 2 \\ 0 & 1 & 0 & 9 \\ 0 & 1 & 0 & 20 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 1 & 13 \\ 0 & 0 & 1 & 22 \end{pmatrix} \times \begin{pmatrix} \beta_{g=1} \\ \beta_{g=2} \\ \beta_{g=3} \\ \beta_{1} \end{pmatrix} + \begin{pmatrix} \varepsilon_{1} \\ \varepsilon_{2} \\ \varepsilon_{3} \\ \varepsilon_{4} \\ \varepsilon_{5} \\ \varepsilon_{6} \\ \varepsilon_{7} \\ \varepsilon_{8} \\ \varepsilon_{9} \end{pmatrix}, \text{ with } \varepsilon_{i} \sim N(0, \sigma^{2})$$

- Left to right: response vector, design matrix, parameter vector, residual vector

ANCOVA: but wait, there's more

The same model via matrix and vector notation:

$$\begin{pmatrix} 25 \\ 14 \\ 68 \\ 79 \\ 64 \\ 139 \\ 49 \\ 111 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 14 \\ 1 & 0 & 0 & 22 \\ 0 & 1 & 0 & 2 \\ 0 & 1 & 0 & 9 \\ 0 & 1 & 0 & 20 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 1 & 13 \\ 0 & 0 & 1 & 22 \end{pmatrix} \times \begin{pmatrix} \beta_{g=1} \\ \beta_{g=2} \\ \beta_{g=3} \\ \beta_{1} \end{pmatrix} + \begin{pmatrix} \varepsilon_{1} \\ \varepsilon_{2} \\ \varepsilon_{3} \\ \varepsilon_{4} \\ \varepsilon_{5} \\ \varepsilon_{6} \\ \varepsilon_{7} \\ \varepsilon_{8} \\ \varepsilon_{9} \end{pmatrix}, \text{ with } \varepsilon_{i} \sim \text{N}(0, \sigma^{2})$$

• The value of the linear predictor for the first data point is given by

$$1 \cdot \beta_{g=1} + 0 \cdot beta_{g=2} + 0 \cdot beta_{g=3} + 1 \cdot \beta_1$$

A trick for learning about the design matrix in R: model.matrix()

```
1 # Means parameterization
 2 X ij \leftarrow model.matrix(\sim A - 1 + X)
  3 X ij \# rows = i, j = columns
  A1 A2 A3 X
 1 0 0 1
2 1 0 0 14
7 0 0 1 2
8 0 0 1 13
attr(,"assign")
[1] 1 1 1 2
attr(,"contrasts")
attr(, "contrasts") $A
[1] "contr.treatment"
```

• see also effects or treatment contrast parameterization

```
model.matrix(\sim A + X)
```

The ANCOVA in Stan

- The code looks very similar to the algebraic specification of this linear model
 - Note I am picking vague-ish priors but the specific priors aren't the point of this lesson

The ANCOVA. stan file

```
1 data {
3 int<lower=0> n col;  // columns of design matrix = j
4 vector[n obs] y obs; // observed data
   matrix[n obs, n col] X ij; // design matrix: model.matrix(~A-1+X)
  parameters {
   vector[n_col] b j; // one parameter for each column of Xij
   real<lower=0> sig; // sigma must be postive
10 }
11 model {
  b_j ~ normal(0,100); // priors for b_j
14 \operatorname{sig} \sim \operatorname{normal}(0, 100); // prior for \operatorname{sig}
15  y_pred = X_ij * b j;  // linear algebra sneakery
16 y obs ~ normal(y pred, sig); // likelihood
17 }
```

And the corresponding R code:

```
1 library(cmdstanr)
 2 mod <- cmdstan model("week3/soln files/ANCOVA.stan") # compile</pre>
 4 # names in tagged list correspond to the data block in the Stan program
 5 X ij \leftarrow model.matrix(\sim A - 1 + X)
 6 stan data \leftarrow list(n obs = nrow(X ij), n col = ncol(X ij),
                      y obs = my dfy, X ij = as.matrix(X ij)
10 # write a function to get starting values
11 inits <- function() {</pre>
12
     list(
13
       b j = jitter(rep(0, ncol(X ij)), amount = 0.5),
14
       sig = jitter(10, 1)
15
16 }
17
18 fit <- mod$sample(</pre>
     data = stan data,
    init = inits,
20
21
    seed = 1, # ensure simulations are reproducible
     chains = 4, # multiple chains
23
     iter warmup = 1000, # how long to warm up the chains
     iter sampling = 1000, # how many samples after warmp
24
     parallel chains = 4 # run them in parallel?
26 )
```

Note this is all in the solution file for this week

Break

- Now we will move into Generalized Linear Models (GLM),
 where all of the information we just learned still applies
- Primary difference for GLMs is that they will allow us to model non-normal response variables in a manner similar to what we just did with an ANCOVA
 - Do this via a link function

Generalized Linear Models (GLMs)

- The GLM is a flexible generalization of linear regression, developed by Nelder and Wedderburn in 1972 while working together at the Rothamsted Experimental Station in the U.K.
- Extend the concept of linear effect of covariates to response variables for statistical distributions where something other than a normal is assumed
 - e.g., Poisson, binomial/Bernoulli, gamma, exponential, etc.
- Linear effect of covariates is expressed not for the expected response directly, but rather for a transformation of the expected response (McCullagh and Nelder 1989)
- Unifies various statistical methods, and thus fundamental to much contemporary statistical modeling

Generalized Linear Models (GLMs)

- The linear effect of covariates is expressed not for the expected response directly, but for a transformation of the expected response (Kery and Royle 2016)
 - This transformation is called a link function

We generally describe a GLM for a response y_i in terms of three things:

- 1. A random component (i.e., the likelihood)
- 2. A link function (i.e., a mathematical transformation)
- 3. Systematic component (i.e., the linear predictor)

The three parts of a GLM

1. Random component of the response: a statistical distribution f with parameter(s) θ :

$$y_i \sim f(heta)$$

2. A link function g, which is applied to the expected response $E(y) = \mu_i$, with η_i known as the linear predictor:

$$g(E(y)) = g(\mu_i) = \eta_i$$

3. Systematic part of the response (mean structure of the model containing a linear model):

$$\eta_i = eta_0 + eta_1 \cdot x_i$$

We can combine elements 2 and 3 and define a GLM succinctly as:

$$egin{aligned} y_i \sim f(heta) \ g(\mu_i) = eta_0 + eta_1 \cdot x_i \end{aligned}$$

- A response y follows a distribution f with parameter(s) θ , and a transformation g of the expected response, which is modeled as a linear function of covariates
- This is how we will code them in Stan, which makes the Bayesian framework powerful for learning GLMs

Thinking about distributions

Common distributions for data

Discrete

Name	Notation	Domain	Range
Bernoulli	$B \sim Bernoulli(p)$	$0 \le p \le 1$	$B \in \{0,1\}$
Binomial	$N \sim Binomial(p, n)$	$0 \le p \le 1$	$N \in \{0,1,\dots,n\}$
Poisson	$N\sim Poisson(\lambda)$	λ>0	$N \in \{0,1,2,\dots\}$
Negative binomial	$N\sim Negative Binomial(\lambda, \theta)$	λ>0 θ>0	$N \in \{0,1,2,\}$
Conway-Maxwell- Poisson	$N\sim CMP(\mu,\nu)$	μ>0 ν>0	$N \in \{0,1,2,\}$

Thinking about distributions

Common distributions for data

Continuous

Name	Notation	Domain	Range
Normal	$Y \sim Normal(\mu, \sigma^2)$	$\sigma^2 > 0$	Unrestricted
Lognormal	$Y \sim Lognormal(\mu, \sigma^2)$ which is similar to $log(Y) \sim Normal(\mu, \sigma^2)$	$\sigma^2 > 0$	Y > 0
Gamma	Y~Gamma(μ, CV)	μ > 0 CV > 0	Y > 0
Beta	$p \sim Beta(\alpha, \beta)$	$\alpha > 0$, $\beta > 0$	0 < p < 1
	μ = σσσσ (σσ, μ)	от о, р	- P

Justin Bois' Distribution explorer

https://distribution-explorer.github.io/

Thinking about link functions

Common link functions

Name	Notation	Implies that	Range
Identify	$\lambda_i = \mathbf{x}_i \mathbf{\beta}$	$\lambda_i = \mathbf{x}_i \mathbf{\beta}$	$-\infty < \lambda_i < \infty$
Log	$\log(\lambda_i) = \mathbf{x}_i \mathbf{\beta}$	$\lambda_i = \exp(\mathbf{x}_i \mathbf{\beta})$	$0 < \lambda_i < \infty$
Logit	$\operatorname{logit}(\lambda_i) = \mathbf{x}_i \mathbf{\beta}$	$\lambda_i = \operatorname{logistic}(\mathbf{x}_i \boldsymbol{\beta})$	$0 < \lambda_i < 1$

Why you should care part I

- GLM concept gives you considerable creative freedom in combining the three components
 - However, there are typically pairs of response distributions and link functions that go well together
 - These are called *canonical* link functions
 - Identity link for normal responses
 - Log link for Poisson responses
 - Logit link for binomial or Bernoulli responses

Why you should care part II

- Bernoulli/binomial: survival, maturity, presence/absence, data either 0 or 1
- Poisson: abundance, recruitment, unbounded counts [0, Inf]
- Many exciting ecological models can be viewed as coupled GLMs
- GLMs are defined for all members of statistical distributions belonging to the so-called "exponential family" (McCullagh and Nelder 1989; Dobson and Barnett 2008)
 - normal, Poisson, binomial/Bernoulli, multinomial, beta, gamma, lognormal, exponential, and Dirichlet
- Principles of linear modeling can be carried over to models other than normal linear regression

The Poisson GLM for unbounded counts

$$egin{aligned} C_i \sim \operatorname{Poisson}(\lambda_i) \ \log(\lambda_i) = X_{i,j} \cdot eta_{\mathbf{j}} \end{aligned}$$

- C is count of observation $i, X_{i,j}$ is a design matrix, j is number of columns, β_j is a vector of parameters
- simulate Poisson data in R:

```
1  set.seed(1)
2  rpois(n = 100, lambda = 15) # 100 deviates from lambda = 15

[1] 12 20 19 16  9 16 17 17 13 20 16 12 13 13 15 11 18 17 18 18 15  7 16 19
12

[26] 13 16 20 14 16 14  9 18 13 19 13 21 17 13 11 12  8 17 14 18 16 12 11 20
22

[51] 13 10 10 24 14 17 15 12  9 20 15 23 16 12 14 17 19 15 14 11 12 19 17 14
13
```

The Poisson GLM for unbounded counts

$$egin{aligned} C_i \sim \operatorname{Poisson}(\lambda_i) \ \log(\lambda_i) = X_{i,j} \cdot eta_{\mathbf{j}} \end{aligned}$$

- C is count of observation $i, X_{i,j}$ is a design matrix, j is number of columns, β_j is a vector of parameters
- log-probability mass of Poisson count data in R:

```
1 C_i <- c(10, 17, 18) # fake count data
2 dpois(x = C_i, lambda = 15, log = TRUE) # return log-Poisson likelihood
[1] -3.023911 -2.468220 -2.650542
```

The Poisson GLM for unbounded counts

$$egin{aligned} C_i \sim \operatorname{Poisson}(\lambda_i) \ \log(\lambda_i) = X_{i,j} \cdot eta_{\mathbf{j}} \end{aligned}$$

- Assumptions
 - The mean and variance of the Poisson distribution are equal
 - Almost never holds and usually requires a negative binomial or another model structure
 - Causes of over/under dispersion are complex

Testing for over- or under-dispersion: Poisson GLM

- mean = variance = λ
- Another way: Bayesian p-value
- Idea: define a test statistic and compare the posterior distribution of that statistic for the original data to the posterior distribution of that test statistic for "replicate" datasets
- Note we could also use graphical posterior predictive checks

Bayesian p-value

Pearson residuals:

$$D\left(y_i, heta
ight) = rac{\left(y_i - \mathrm{E}\left(y_i
ight)
ight)}{\sqrt{\mathrm{Var}(y_i)}}.$$

 Begin by calculating the sum of squared residuals (our test statistic) for the observed data:

$$T(\mathbf{y}, heta) = \sum_i D(y_i, heta)^2$$

Bayesian p-value

 Next, we calculate the same statistic for replicate (simulated) datasets

$$T\left(\mathbf{y}^{ ext{new}}, heta
ight) = \sum_{i} Dig(y_{i}^{ ext{new}}, hetaig)^{2}$$

- Bayesian p-value is simply the posterior probability $\Pr(T\left(\mathbf{y}^{\mathrm{new}}\right) > T(\mathbf{y}))$
- Should be close to 0.5 for a good model, too near 0 or 1 indicates lack of fit (somewhat subjective)

The binomial GLM for bounded counts or proportions

- Often have counts bounded by an upper limit
 - Number of successful breeding pairs cannot be higher than all observed breeding pairs
- Proportion of nestlings surviving
- These types of data require the binomial GLM

The binomial GLM for bounded counts or proportions

1. Random part of the response (statistical distribution)

$$C_i \sim \operatorname{Binomial}(N_i, p_i)$$

2. Link of the random and systematic bit (logit link):

$$\operatorname{logit}(p_i) = \operatorname{log}\!\left(rac{p_i}{1-p_i}
ight) = \eta_i$$

3. Systematic part (linear predictor):

$$\eta_i = \beta_0 + {\beta_1}^* X_i + {\beta_2}^* X_i^2$$

The binomial GLM for bounded counts or proportions

$$C_i \sim \operatorname{Binomial}(N_i, p_i)$$

$$\operatorname{logit}(p_i) = \operatorname{log}\!\left(rac{p_i}{1-p_i}
ight) = \eta_i$$

$$\eta_i = \beta_0 + {\beta_1}^* X_i + {\beta_2}^* X_i^2$$

- ullet where p_i is expected proportion on arithmetic scale and is mean response of each of the observed N_i trials
- η_i is the same proportion but on the logit-link scale

The binomial GLM for bounded counts or proportions

$$\operatorname{logit}(p_i) = \operatorname{log}\!\left(rac{p_i}{1-p_i}
ight) = \eta_i$$

- Logit maps the probability scale (i.e., range 0 to 1) to the entire real line (i.e., $-\infty$ to ∞)
- The rest of the model (linear predictor) is up to you, your data, your questions, and your imagination

Overdispersion and underdispersion in the binomial distribution

Note that the binomial distribution variance is equal to

$$N \cdot p \cdot (1-p)$$

- Need to check the binomial for under and over dispersion similar to how we check for the Poisson
- See this paper for some useful logistic regression checks

In-class exercise

In-class exercise

 Let's simulate a Poisson GLM, where we model peninsular homing clam counts as a function of year:

$$C_i \sim ext{Poisson}(\lambda_i) \ \log(\lambda_i) = eta_0 + eta_1 \cdot ext{year}_i + eta_2 \cdot ext{year}_i^2 + eta_3 \cdot ext{year}_i^3$$

- Clam counts follow a cubic polynomial function of time
 - Note this equation is still linear in the predictors
- Where do we begin?

Peninsular homing clams (**): simulating fake data

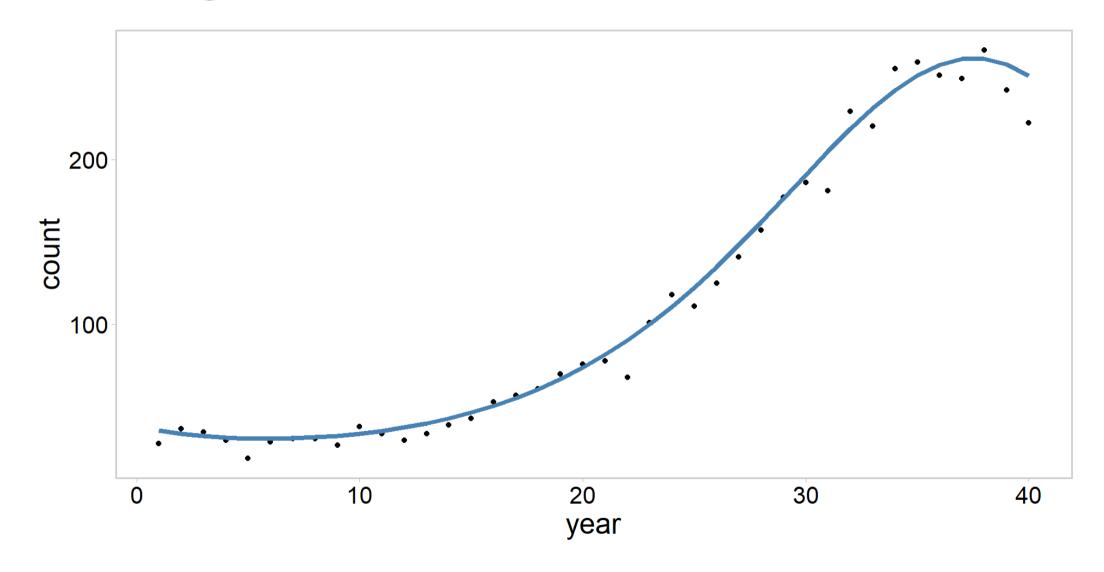

Let's get it started (in here)

```
1  n_year <- 40
2  beta0 <- 3.5576
3  beta1 <- -0.0912
4  beta2 <- 0.0091
5  beta3 <- -0.00014
6  set.seed(1)</pre>
```

- Exercise: see if you can generate fake data for this model
- Start by calculating the systematic component, then apply the link function, and lastly generate random deviates according to the Poisson distribution

Homing clam simulation solution

Coding the model in Stan

- Assume Normal(0, 10) priors for everything
- Should look similar to the simulation code
- Hint: you will get a funny error message and we will work through it as a group

Writing the clams.stan file

```
1 data {
2    ...
3 }
4 parameters {
5    ...
6 }
7 transformed parameters {
8    ...
9 }
10 model {
11    ...
12 }
```

Work together to get this model estimating

Go to solution files

Summary and Recap

- We have covered much ground
- Statistical models as response = deterministic + random
 - ANCOVA
- Introduced GLMs, which allow us to model data coming from distributions other than the normal
- Examined Poisson and Binomial GLMs
- Talked about dispersion
- This material lays the foundation for more complicated models
